

Virtual Machine

Part I: Stack Arithmetic

Usage and Copyright Notice:

Copyright 2005 © Noam Nisan and Shimon Schocken

This presentation contains lecture materials that accompany the textbook “The Elements of Computing Systems” by Noam Nisan & Shimon Schocken, MIT Press, 2005.

We provide both PPT and PDF versions.

The book web site, www.idc.ac.il/tecs , features 13 such presentations, one for each book chapter. Each presentation is designed to support about 3 hours of classroom or self-study instruction.

You are welcome to use or edit this presentation as you see fit for instructional and non-commercial purposes.

If you use our materials, we will appreciate it if you will include in them a reference to the book's web site.

If you have any questions or comments, you can reach us at tecs.ta@gmail.com

Where we are at:

Motivation

```
class Main {
  static int x;

  function void main() {
    // Input and multiply 2 numbers
    var int a, b, x;
    let a = Keyboard.readInt("Enter a number");
    let b = Keyboard.readInt("Enter a number");
    let x = mult(a,b);
    return;
  }
}

// Multiplies two numbers.
function int mult(int x, int y) {
  var int result, j;
  let result = 0; let j = y;
  while not(j = 0) {
    let result = result + x;
    let j = j - 1;
  }
  return result;
}
```

Ultimate goal:

Translate high-level programs into executable code.

Compiler

```
...
@a
M=D
@b
M=0
(LOOP)
@a
D=M
@b
D=D-A
@END
D; JGT
@j
D=M
@temp
M=D+M
@j
M=M+1
@LOOP
0; JMP
(END)
@END
0; JMP
...
```

Compilation models

direct compilation:

requires $n \cdot m$ translators

2-tier compilation:

requires $n + m$ translators

Two-tier compilation:

- First compilation stage depends only on the details of the source language
- Second compilation stage depends only on the details of the target platform.

The big picture

The intermediate code:

- The interface between the 2 compilation stages
- Must be sufficiently general to support many <high-level language, machine language> pairs
- Can be modeled as the language of an abstract virtual machine (VM)
- Can be implemented in many different ways.

The big picture

Lecture plan

Goal: Specify and implement a VM model and language

Arithmetic / Boolean commands

add
sub
neg
eq
gt
lt
and
or
not

This lecture

Memory access commands

pop x (variable)
push y (variable or constant)

Program flow commands

label (declaration)
goto (label)
if-goto (label)

Next lecture

Function calling commands

function (declaration)
call (a function)
return (from a function)

Method: (a) specify the abstraction (model's constructs and commands)
(b) propose how to implement it over the Hack platform.

The VM language

Important:

From here till the end of this and the next lecture we describe the VM model used in the Hack-Jack platform

Other VM models (like JVM/JRE and IL/CLR) are similar in spirit and different in scope and details.

Our VM features a single 16-bit data type that can be used as:

- Integer
- Boolean
- Pointer.

Stack arithmetic

■ Typical operation:

- Pops topmost values x, y from the stack
- Computes the value of some function $f(x, y)$
- Pushes the result onto the stack

(Unary operations are similar, using x and $f(x)$ instead)

■ Impact: the operands are replaced with the operation's result

■ In general: all arithmetic and Boolean operations are implemented similarly.

Memory access (first approximation)

Memory access (first approximation)

- Classical data structure
- Elegant and powerful
- Many implementation options.

Evaluation of arithmetic expressions

```
// d=(2-x)*(y+5)
push 2
push x
sub
push y
push 5
add
mult
pop d
```

Evaluation of Boolean expressions

```
// if (x<7) or (y=8)
push x
push 7
lt
push y
push 8
eq
or
```

Arithmetic and Boolean commands (wrap-up)

Command	Return value (after popping the operand/s)	Comment
add	$x + y$	Integer addition (2's complement)
sub	$x - y$	Integer subtraction (2's complement)
neg	$-y$	Arithmetic negation (2's complement)
eq	true if $x = y$ and false otherwise	Equality
gt	true if $x > y$ and false otherwise	Greater than
lt	true if $x < y$ and false otherwise	Less than
and	$x \text{ And } y$	Bit-wise
or	$x \text{ Or } y$	Bit-wise
not	Not y	Bit-wise

Memory access (motivation)

Modern programming languages normally feature the following variable kinds:

- Class level

- Static variables
- Private variables (AKA "object variables" / "fields" / "properties")

- Method level:

- Local variables
- Argument variables

A VM abstraction must support (at least) all these variable kinds.

The memory of our VM model consists of 8 memory segments:

`static`, `argument`, `local`, `this`, `that`, `constant`, `pointer`, and `temp`.

Memory access commands

Command format:

pop *segment i*

push *segment i*

(Rather than **pop** *x* and **push** *y*,
as was shown in previous slides,
which was a conceptual simplification)

Where *i* is a non-negative integer and *segment* is one of the following:

- **static**: holds values of global variables, shared by all functions in the same class
- **argument**: holds values of the argument variables of the current function
- **local**: holds values of the local variables of the current function
- **this**: holds values of the private ("object") variables of the current object
- **that**: holds array values
- **constant**: holds all the constants in the range 0...32767 (pseudo memory segment)
- **pointer**: used to align **this** and **that** with different areas in the heap
- **temp**: fixed 8-entry segment that holds temporary variables for general use; Shared by all VM functions in the program.

VM programming

- VM programs are normally written by *compilers*, not by humans
- In order to write compilers, it helps to understand the spirit of VM programming. So we will now see how some common programming tasks can be implemented in the VM abstraction:
 - Arithmetic task
 - Object handling task
 - Array handling task

Disclaimer:

These programming examples don't belong here; They belong to the compiler chapter, since expressing programming tasks in the VM language is the business of the compiler (e.g., translating Java programs to Bytecode programs)

We discuss them here to give some flavor of programming at the VM level.

(One can safely skip from here to slide 21)

Arithmetic example

High-level code

```
function mult(x,y) {  
  int result, j;  
  result=0;  
  j=y;  
  while ~(j=0) {  
    result=result+x;  
    j=j-1;  
  }  
  return result;  
}
```

Just after mult(7,3) is entered:

Just after mult(7,3) returns:

VM code (first approx.)

```
function mult(x,y)  
  push 0  
  pop result  
  push y  
  pop j  
  label loop  
  push j  
  push 0  
  eq  
  if-goto end  
  push result  
  push x  
  add  
  pop result  
  push j  
  push 1  
  sub  
  pop j  
  goto loop  
  label end  
  push result  
  return
```

VM code

```
function mult 2  
  push constant 0  
  pop local 0  
  push argument 1  
  pop local 1  
  label loop  
  push local 1  
  push constant 0  
  eq  
  if-goto end  
  push local 0  
  push argument 0  
  add  
  pop local 0  
  push local 1  
  push constant 1  
  sub  
  pop local 1  
  goto loop  
  label end  
  push local 0  
  return
```

Object handling example

```
/* Assume that b and r were
passed to the function as
its first two arguments.
The following code
implements the operation
b.radius=r. */
```

```
// Get b's base address:
push argument 0
// Point the this seg. to b:
pop pointer 0
// Get r's value
push argument 1
// Set b's third field to r:
pop this 2
```

Virtual memory segments just before
the operation `b.radius=17`:

argument	pointer	this
0 3012	0	0
1 17	1	...
...		

Virtual memory segments just after
the operation `b.radius=17`:

argument	pointer	this
0 3012	0 3012	0 120
1 17	1	1 80
...		2 17
		3 3
		...

(this 0
is now
aligned with
RAM[3012])

Array handling example

```
/* Assume that bar is the
first local variable declared
in the high-level program. The
code below implements
bar[2]=19, or *(bar+2)=19. */
```

```
// Get bar's base address:
push local 0
push constant 2
add
// Set that's base to (bar+2):
pop pointer 1
push constant 19
// *(bar+2)=19:
pop that 0
```

Virtual memory segments
Just before the `bar[2]=19` operation:

local		pointer		that	
0	4315	0		0	
1	...	1		1	...

Virtual memory segments
Just after the `bar[2]=19` operation:

local		pointer		that	
0	4315	0	4317	0	19
1	...	1		1	...

(that 0
is now
aligned with
RAM[4317])

Lecture plan

Goal: Specify and implement a VM model and language

Arithmetic / Boolean commands

add
sub
neg
eq
gt
lt
and
or
not

This lecture

Memory access commands

pop segment i
push segment i

Program flow commands

label (declaration)
goto (label)
if-goto (label)

Next lecture

Function calling commands

function (declaration)
call (a function)
return (from a function)

Method: (a) specify the abstraction (model's constructs and commands)
 (b) propose how to implement it over the Hack platform.

Implementation

VM implementation options:

- Software-based (emulation)
- Translator-based (e.g., to the Hack language)
- Hardware-based (CPU-level)

Well-known translator-based implementations:

- JVM (runs bytecode programs in the Java platform)
- CLR (runs IL programs in the .NET platform).

Our VM emulator (part of the course software suite)

The screenshot shows the Virtual Machine Emulator (1.4b3) interface. The title bar indicates the file path is G:\examples\add. The menu bar includes File, View, Run, and Help. The toolbar contains icons for file operations, execution (single step, multi step, break), and animation (slow, fast). The main window is divided into several panels:

- Program:** A list of instructions. Instruction 11, 'add', is highlighted in yellow and labeled 'VM code'.
- Static:** A table for static variables.
- Local:** A table for local variables. It contains three entries: index 0 with value 15, index 1 with value 8, and index 2 with value 0. This panel is labeled 'virtual memory segments'.
- Argument:** A table for arguments.
- This:** A table for 'this' pointer.
- That:** A table for 'that' pointer.
- Temp:** A table for temporary variables.
- Stack:** A table showing the current stack state with values 15 and 8. It is labeled 'working stack'.
- Call Stack:** A list of active functions: Sys.init, Main.main, and Main.add.
- emulator controls:** A box containing the 'Animate' dropdown (set to 'Program flow'), 'View' dropdown (set to 'Script'), and 'Format' dropdown (set to 'Decimal').
- default test script:** A box containing the script:

```
repeat {  
  vmstep;  
}
```
- global stack:** A table showing memory addresses and values. Address 271 is highlighted in yellow.
- host RAM:** A table showing memory addresses and values. Address 271 is highlighted in yellow. A blue note next to it says '(the RAM is not part of the VM)'. The table includes registers SP, LCL, ARG, THIS, THAT, and Temp0 through Temp7, R13, and R14.

VM implementation on the Hack platform

The challenge: (i) map the VM constructs on the host RAM, and (ii) given this mapping, figure out how to implement each VM command using assembly commands that operate on the RAM

■ **local, argument, this, that**: mapped on the heap. The base addresses of these segments are kept in **LCL, ARG, THIS, THAT**. Access to the i -th entry of a segment is implemented by accessing the segment's $(\text{base} + i)$ word in the RAM

■ **static**: static variable number j in a VM file f is implemented by the assembly language symbol $f.j$ (and recall that the assembler maps such symbols to the RAM starting from address 16)

■ **constant**: truly a virtual segment. Access to **constant i** is implemented by supplying the constant i

■ **pointer, temp**: see the book

Exercise: given the above game rules, write the Hack commands that implement, say, **push constant 5** and **pop local 2**.

Parser module (proposed design)

Parser: Handles the parsing of a single .vm file, and encapsulates access to the input code. It reads VM commands, parses them, and provides convenient access to their components. In addition, it removes all white space and comments.

Routine	Arguments	Returns	Function
Constructor	Input file / stream	--	Opens the input file/stream and gets ready to parse it.
hasMoreCommands	--	boolean	Are there more commands in the input?
advance	--	--	Reads the next command from the input and makes it the current command. Should be called only if hasMoreCommands () is true. Initially there is no current command.
commandType	--	C_ARITHMETIC, C_PUSH, C_POP, C_LABEL, C_GOTO, C_IF, C_FUNCTION, C_RETURN, C_CALL	Returns the type of the current VM command. C_ARITHMETIC is returned for all the arithmetic commands.
arg1	--	string	Returns the first argument of the current command. In the case of C_ARITHMETIC, the command itself (add, sub, etc.) is returned. Should not be called if the current command is C_RETURN.
arg2	--	int	Returns the second argument of the current command. Should be called only if the current command is C_PUSH, C_POP, C_FUNCTION, or C_CALL.

CodeWriter module (proposed design)

CodeWriter: Translates VM commands into Hack assembly code.			
Routine	Arguments	Returns	Function
Constructor	Output file / stream	--	Opens the output file/stream and gets ready to write into it.
setFileName	fileName (string)	--	Informs the code writer that the translation of a new VM file is started.
writeArithmetic	command (string)	--	Writes the assembly code that is the translation of the given arithmetic command.
WritePushPop	Command (C_PUSH or C_POP), segment (string), index (int)	--	Writes the assembly code that is the translation of the given command, where command is either C_PUSH or C_POP.
Close	--	--	Closes the output file.
Comment: More routines will be added to this module in chapter 8.			

Perspective

- In this lecture we began the process of building a compiler
- Modern compiler architecture:
 - Front end (translates from high level language to a VM language)
 - Back end (implements the VM language on a target platform)
- Brief history of virtual machines:
 - 1970's: p-Code
 - 1990's: Java's JVM
 - 2000's: Microsoft .NET
- A full blown VM implementation typically includes a common software library (can be viewed as a mini, portable OS).
- We will build such a mini OS later in the course.

The road ahead

Tasks:

- Complete the VM specification and implementation (chapters 7,8)
- Introduce Jack, a high-level programming language (chapter 9)
- Build a compiler for it (chapters 10,11)
- Finally, build a mini-OS, i.e. a run-time library (chapter 12).

Conceptually similar to:

- JVM
- Java
- Java compiler
- JRE

And to:

- CLR
- C#
- C# compiler
- .NET base class library
